Formalization of Randomized Approximation Algorithms for Frequency Moments

Emin Karayel

January 18, 2022

Abstract

In 1999 Alon et. al. introduced the still active research topic of approximating the frequency moments of a data stream using randomized algorithms with minimal spage usage. This includes the problem of estimating the cardinality of the stream elements—the zeroth frequency moment. But, also higher order frequency moments that provide information about the skew of the data stream, which is for example critical information for parallel processing. The frequency moment of a data stream $a_1, \ldots, a_m \in U$ can be defined as $F_k := \sum_{u \in U} C(u, a)^k$ where $C(u, a)$ is the count of occurences of u in the stream a. They introduce both lower bounds and upper bounds, which were later improved by newer publications. The algorithms have guaranteed success probability and accuracy, without making any assumptions on the input distribution. They are an interesting use-case for formal verification, because they rely on deep results from both algebra and analysis, require a large body of existing results. This work contains the formal verification of three algorithms for the approximation of F_0, F_2 and F_k for $k \geq 3$. To achieve it, the formalization also includes reusable components common to all algorithms, such as universal hash families, the median method, formal modelling of one-pass data stream algorithms and a generic flexible encoding library for the verification of space complexities.

1 Encoding

theory *Encoding*
imports *Main HOL−Library.Sublist HOL−Library.Extended-Real HOL−Library.FuncSet HOL.Transcendental*
begin

This section contains a flexible library for encoding high level data structures into bit strings. The library defines encoding functions for primitive types, as well as combinators to build encodings for more complex types. It is used to measure the size of the data structures.

2 Field

theory *Field*
imports *Main HOL*−*Algebra.Ring-Divisibility HOL*−*Algebra.IntRing*
begin

This section contains a proof that the factor ring *ZFact p* for *prime p* is a field. Note that the bulk of the work has already been done in HOL-Algebra, in particular it is established that *ZFact p* is a domain.

However, any domain with a finite carrier is already a field. This can be seen by establishing that multiplication by a non-zero element is an injective map between the elements of the carrier of the domain. But an injective map between sets of the same non-finite cardinality is also surjective. Hence we can find the unit element in the image of such a map.

Additionally the canonical bijection between *ZFact p* and {*0*..<*p*} is introduced, which is useful for hashing natural numbers.

11.1 Interpolation Polynomials

It is well known that over any field there is exactly one polynomial with degree at most $k - 1$ interpolating k points. That there is never more that one such polynomial follow from the fact that a polynomial of degree $k - 1$ cannot have more than $k - 1$ roots. This is already shown in HOL-Algebra in *field.size-roots-le-degree*. Existence is usually shown using Lagrange interpolation.

In the case of finite fields it is actually only necessary to show either that there is at most one such polynomial or at least one - because a function whose domain and co-domain has the same finite cardinality is injective if and only if it is surjective.

In the following a more generic result (over finite fields) is shown, counting the number of polynomials of degree $k + n - 1$ interpolating k points for non-negative n. As it turns out there are $(card\ (carrier\ F))^n$ such polynomials. The trick is to observe that, for a given fix on the coefficients of order k to $k + n - 1$ and the values at k points there is at most one fitting polynomial.

An alternative way of stating the above result is that there is bijection between the polynomials of degree $n + k - 1$ and the product space $F^k \times F^n$ where the first component is the evaluation of the polynomials at k distinct points and the second component are the coefficients of order at least k.

definition *split-poly* **where** *split-poly F K p* =
(*restrict* (*ring.eval F p*) *K*, λk. *ring.coeff F p* (*k*+*card K*))

The bijection *split-poly* returns the evaluation of the polynomial at the points in K and the coefficients of order at least *card K*.

In the following it is shown that its image is a subset of the product space mentioned above, and that *split-poly* is injective and finally that its image is exactly that product space using cardinalities.

13 Universal Hash Families

theory *Universal-Hash-Families*

imports *Main Interpolation-Polynomial-Counts Product-PMF-Ext*
begin

A k-universal hash family $\mathcal{H}$ is probability space, whose elements are hash functions with domain U and range $i.i < m$ such that:

- For every fixed $x \in U$ and value $y < m$ exactly $\frac{1}{m}$ of the hash functions map x to y: $P_{h \in \mathcal{H}}\,(h(x) = y) = \frac{1}{m}$.
- For at most k universe elements: $x_1, \cdots, x_m$ the functions $h(x_1), \cdots, h(x_m)$ are independent random variables.

In this section, we construct k-universal hash families following the approach outlined by Wegman and Carter using the polynomials of degree less than k over a finite field.

A hash function is just polynomial evaluation.

theory *Frequency-Moment-0*
imports *Main Primes-Ext Float-Ext Median K-Smallest Universal-Hash-Families-Nat Encoding*
Frequency-Moments Landau-Ext
begin

This section contains a formalization of the algorithm for the zero-th frequency moment. It is a KMV algorithm with a rounding method to match the space complexity of the best algorithm described in [2].

In addition ot the Isabelle proof here, there is also and informal handwrittend proof in Appendix A.

A Informal proof of correctness for the F_0 algorithm

This section contains a detailed informal proof for the correctness of the F_0-algorithm. Because of the standard amplification result about medians (see for example [1]) it is enough to show that each of the estimates the median is taken from is within the desired interval with success probability $\frac{2}{3}$.
To verify the latter, let $a_1, \ldots, a_m$ be the stream elements, where we assume that the elements are a subset of $\{0, \ldots, n-1\}$ and $0 < \delta < 1$ be the desired relative accuracy. Let p be the smallest prime such that $p \geq \max(n, 19)$ and let h be a random polynomial over $GF(p)$ with degree strictly less than 2. The algoritm also introduces the internal parameters t, r defined by:

$$\begin{aligned} t &:= \lceil 80\delta^{-2} \rceil \\ r &:= 4\log_2 \lceil \delta^{-1} \rceil + 24 \end{aligned}$$

The estimate the algorithm obtains is:

$$A := \{a_1, \ldots, a_m\} \qquad H := \{\lfloor h(a) \rfloor_r | a \in A\}$$

$$R := \begin{cases} tp\,(\min_t(H))^{-1} & \text{if } |H| \geq t \\ |H| & \text{othewise,} \end{cases}$$

Here $\min_t(H)$ denotes the t-th smallest element of H. With these definitions, it is possible to state the goal as:

$$P(|R - F_0| \leq \delta |F_0|) \geq \frac{2}{3}.$$

which is shown by separately in the following two subsections for the cases $F_0 \geq t$ and $F_0 < t$.

A.1 Case $F_0 \geq t$

Let us introduce:

$$\begin{aligned} H^* &:= \{h(a) | a \in A\}^{\#} \\ R^* &:= tp\left(\text{rank}_t^{\#}(H^*)\right)^{-1} \end{aligned}$$

These definitions correspond to the H, R but with a few minor modifications. The set H^* is a multiset, this means that each element also has a multiplicity, counting the number of *distinct* elements of A being mapped by h to the same value. Note that by definition: $|H^*| = |A|$. Similarly the operation $\min_t^{\#}$ obtains the t-th element of the multiset H (taking multiplicities into account). Note also that there is no rounding operation $\lfloor \cdot \rfloor_r$ in the definition of H^*. The key reason for the introduction of these alternative versions of H, R is that it is easier to show probabilistic bounds on the distances $|R^* - F_0|$ and $|R^* - R|$ as opposed to $|R - F_0|$ directly. In particular the plan is to show:

$$\delta' := \frac{3}{4}\delta \tag{1}$$

$$P\left(|R^* - F_0| > \delta' F_0\right) \leq \frac{2}{9}, \text{ and} \tag{2}$$

$$P\left(|R^* - F_0| \leq \delta' F_0 \wedge |R - R^*| > \frac{\delta}{4} F_0\right) \leq \frac{1}{9} \tag{3}$$

I.e. the probability that R^* has not the relative accuracy of $\frac{3}{4}\delta$ is less that $\frac{2}{9}$ and the probability that assuming R^* has the relative accuracy of $\frac{3}{4}\delta$ but that R deviates by more that $\frac{1}{4}\delta F_0$ is at most $\frac{1}{9}$. Hence, the probability that neither of these events happen is at least $\frac{2}{3}$ but in that case:

$$|R - F_0| \leq |R - R^*| + |R^* - F_0| \leq \frac{\delta}{4} F_0 + \frac{3\delta}{4} F_0 = \delta F_0. \tag{4}$$

For the verification of Equation 2 let us introduce:

$$Q(u) = |\{h(a) < u \mid a \in A\}|$$

and observe that $\min_t^{\#}(H^*) < u$ if $Q(u) \geq t$ and $\min_t^{\#}(H^*) \geq v$ if $Q(v) \leq t - 1$. To see why this is true note that, if at least t elements of A are mapped by h below a certain value, then the rank t element must also be within them, and thus also be below that value. And that the opposite direction of this conclusion is also true. Note that this relies on the fact that H^* is a multiset and that multiplicities are being taken into account, when computing the t-th smallest element.

Alternatively, it is also possible to write $Q(u) = \sum_{a \in A} 1_{\{h(a)<u\}}$[1], i.e., Q is a sum of pairwise independent $\{0,1\}$-valued random variables, with expectation $\frac{u}{p}$ and variance $\frac{u}{p} - \frac{u^2}{p^2}$. [2] Using linearity of expectation and Bienaymé's identity, it follows that $\operatorname{Var} Q(u) \leq \operatorname{E} Q(u) = |A|up^{-1} = F_0 up^{-1}$ for $u \in \{0, \ldots, p\}$.

For $v = \left\lfloor \frac{tp}{(1-\delta')F_0} \right\rfloor$ it is possible to conclude:

$$\begin{aligned} t - 1 &\leq^{3} \frac{t}{(1-\delta')} - 3\sqrt{\frac{t}{(1-\delta')}} - 1 \\ &\leq \frac{F_0 v}{p} - 3\sqrt{\frac{F_0 v}{p}} \leq \mathrm{E}Q(v) - 3\sqrt{\mathrm{Var}Q(v)} \end{aligned}$$

and thus using Tchebyshev's inequality:

$$\begin{aligned} P\left(R^* < \left(1-\delta'\right) F_0\right) &= P\left(\mathrm{rank}_t^{\#}(H^*) > \frac{tp}{(1-\delta')F_0}\right) \\ &\leq P(\mathrm{rank}_t^{\#}(H^*) \geq v) = P(Q(v) \leq t-1) \\ &\leq P\left(Q(v) \leq \mathrm{E}Q(v) - 3\sqrt{\mathrm{Var}Q(v)}\right) \leq \frac{1}{9}. \end{aligned} \tag{5}$$

Similarly for $u = \left\lceil \frac{tp}{(1+\delta')F_0} \right\rceil$ it is possible to conclude:

$$\begin{aligned} t &\geq \frac{t}{(1+\delta')} + 3\sqrt{\frac{t}{(1+\delta')} + 1} + 1 \\ &\geq \frac{F_0 u}{p} + 3\sqrt{\frac{F_0 u}{p}} \geq \mathrm{E}Q(u) + 3\sqrt{\mathrm{Var}Q(v)} \end{aligned}$$

and thus using Tchebyshev's inequality:

$$\begin{aligned} P\left(R^* > \left(1+\delta'\right) F_0\right) &= P\left(\mathrm{rank}_t^{\#}(H^*) < \frac{tp}{(1+\delta')F_0}\right) \\ &\leq P(\mathrm{rank}_t^{\#}(H^*) < u) = P(Q(u) \geq t) \\ &\leq P\left(Q(u) \geq \mathrm{E}Q(u) + 3\sqrt{\mathrm{Var}Q(u)}\right) \leq \frac{1}{9}. \end{aligned} \tag{6}$$

To verfiy Equation 3, note that

$$\min_t(H) = \lfloor \min_t^{\#}(H^*) \rfloor_r \tag{7}$$

[1] The notation 1_A is shorthand for the indicator function of A, i.e., $1_A(x) = 1$ if $x \in A$ and 0 otherwise.

[2] A consequence of h being choosen uniformly from a 2-independent hash family.

[3] The verification of this inequality is a lengthy but straightforward calculcation using the definition of δ' and t.

if there are no collisions, induced by the application of $\lfloor h(\cdot) \rfloor_r$ on the elements of A. Even more carefully, note that the equation would remain true, as long as there are no collision within the smallest t elements of H^*. Because Equation 3 needs to be shown only in the case where $R^* \geq (1-\delta')F_0$, i.e., when $\min_t^{\#}(H^*) \leq v$, it is enough to bound the probability of a collision in the range $[0; v]$. Moreover Equation 7 implies $|\min_t(H) - \min_t^{\#}(H^*)| \leq \max(\min_t^{\#}(H^*), \min_t(H))2^{-r}$ from which it is possible to derive $|R^* - R| \leq \frac{\delta}{4}F_0$. Another important fact is that h is injective with probability $1 - \frac{1}{p}$, this is because h is choosen uniformly from the polynomials of degree less than 2. If it is a degree 1 polynomial, it is a linear function on $GF(p)$ and thus injective. Because $p \geq 18$ the probability that h is not injective can be bounded by $1/18$. However, even if h is injective, there is still a possibility of collision, because of the application of the rounding operation $\lfloor \cdot \rfloor_r$. The plan is to bound that probability by $1/18$ as well to show Equation 3.

$$
\begin{aligned}
& P\left(|R^* - F_0| \leq \delta' F_0 \wedge |R - R^*| > \frac{\delta}{4}F_0\right) \\
\leq\ & P\left(R^* \geq (1-\delta')F_0 \wedge \min_t^{\#}(H^*) \neq \min_t(H) \wedge h \text{ inj.}\right) + P(\neg h \text{ inj.}) \\
\leq\ & P\left(\exists a \neq b \in A. \lfloor h(a) \rfloor_r = \lfloor h(b) \rfloor_r \leq v \wedge h(a) \neq h(b)\right) + \frac{1}{18} \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} P\left(\lfloor h(a) \rfloor_r = \lfloor h(b) \rfloor_r \leq v \wedge h(a) \neq h(b)\right) \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} P\left(|h(a) - h(b)| \leq v2^{-r} \wedge h(a) \leq v(1+2^{-r}) \wedge h(a) \neq h(b)\right) \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} \sum_{\substack{a', b' \in \{0,\ldots,p-1\} \wedge a' \neq b' \\ |a'-b'| \leq v2^{-r} \wedge a' \leq v(1+2^{-r})}} P(h(a) = a')P(h(b) = b') \\
\leq\ & \frac{1}{18} + 6\frac{F_0^2 v^2}{p^2}2^{-r} \leq \frac{1}{9}.
\end{aligned}
$$

Which shows that Equation 3 is true and Equation 5 and 6 implies Equation 2, which means the reasoning in Equation 4 confirms:

$$
P(|R - F_0| \leq \delta |F_0|) \geq \frac{2}{3} \tag{8}
$$

The following subsection confirms that this is also true for the remaining case, if $F_0 < t$, concluding the proof.

A.2 Case $F_0 < t$

Note that in this case $|H| \leq F_0 < t$ and thus $R = |H|$, hence the goal is to show that: $P(|H| \neq F_0) \leq \frac{1}{3}$.

The latter can only happen, if there is a collision induced by the application of $\lfloor h(\cdot) \rfloor_r$. As before h is not injective with probability at least $\frac{1}{18}$, hence:

$$\begin{aligned}
& P\left(|R - F_0| > \delta F_0\right) \\
\leq\ & P\left(R \neq F_0\right) \\
\leq\ & \frac{1}{18} + P\left(R \neq F_0 \wedge h \text{ injective}\right) \\
\leq\ & \frac{1}{18} + P\left(\exists a \neq b \in A. \lfloor h(a) \rfloor_r = \lfloor h(b) \rfloor_r\right) \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} P\left(\lfloor h(a) \rfloor_r = \lfloor h(b) \rfloor_r \wedge h(a) \neq h(b)\right) \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} P\left(|h(a) - h(b)| \leq p2^{-r} \wedge h(a) \neq h(b)\right) \\
\leq\ & \frac{1}{18} + \sum_{a \neq b \in A} \sum_{\substack{a', b' \in \{0, \ldots, p-1\} \\ a' \neq b' \wedge |a' - b'| \leq p2^{-r}}} P(h(a) = a') P(h(b) = b') \\
\leq\ & \frac{1}{18} + F_0^2 2^{-r+1} \leq \frac{1}{9}.
\end{aligned}$$

Which concludes the proof. □
